Motivation

- Wildfires causes significant economic and human losses globally
- Small improvement in the fight against wildfire can significantly reduce total damage
- Goal: Improvement of the determination of high-risk zones
- **Method:** Predict the *high-risk-damage probability* for a zone based on real data

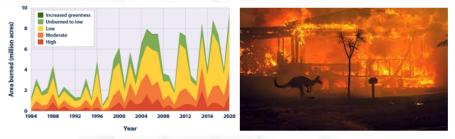

Figure: (left) Damage Caused by Wildfires in the United States, 1984–2020 (right) Bushfire in Australia 2019 (damaged 60-84 million acres)

Applications

- Situation: Existing wildfire
- Question: Which zones to fight to minimize damage?

Figure: Wildfire from above in Turkey 2021

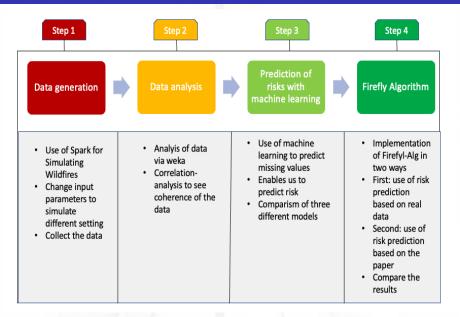

Christian Fuchs, Sascha Wolf

• Answer: Fight zones with highest damage probability

64%	70%	91%
54%	46%	44%
28%	32%	12%
12%	34%	21%

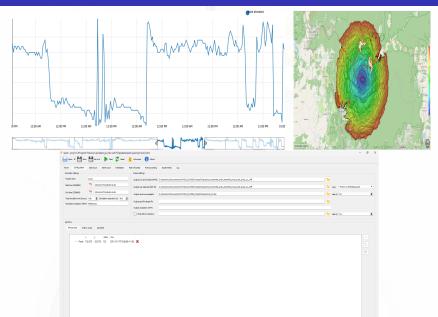

Figure: Categorization in zones with risks

Project roadmap

- Introduction
- Wildfire
- How the Simulation works
- Presenting GUI

Spark

Introduction to Spark

- Spark is a Wildfire Simulation toolkit
- Created by the Research Team of CSIR O Research
- Allows to visualize and output Data
- Can be used for planning, warning, response and manly research

Figure: Matrix

- **Problem:** some feature-values may be unknown which are necessary for risk calculation
- \bullet Goal: Estimate missing values with machine-learning algorithms \rightarrow predict risk for a zone
- Performance measurement:

$$Error_{model} = \sum_{i=1}^{J} |risk_{model} - risk_{expected}|$$

and j = max number of zones

- Training Data: Problem with data generation → partial use of fake data
- Assumption: Expert knowledge for weights
- Provisional risk formula for zone i:

$$risk_{e \times pected} = 0,3 * FlameHeight_i + 0,8 * \frac{1}{ArrivalTime_i}$$

• Desired risk formula for zone i:

 $risk_{e \times pected} = w_1 * FlameHeight_i + w_2 * \frac{1}{ArrivalTime_i} + w_3 * FireIntensity + w_4 * SoilValue..$

• Method 1: Neural network

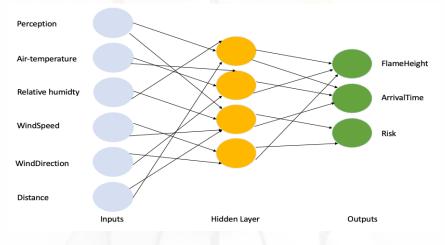

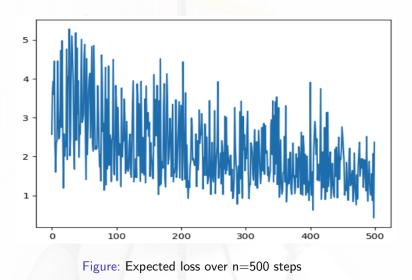

Figure: Trained neural network

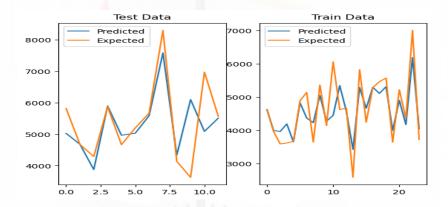

Figure: Plot of risk prediction

• Mean error over n=20 runs: 565

- Method 2: Multi-Output Regressor
- Divides problem into 3 subproblems
- Problem 1: Given X, predict FlameHeight
- Problem 2: Given X and FlameHeight, predict ArrivaTime
- Problem 3: Given X, FlameHeight and ArrivalTime, predict Risk

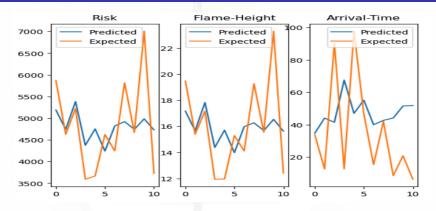

Figure: Plot of risk, arrival-time and flame-height prediction

Mean error: 707

• Neural Network (565) performs better than the Multi-Output Regressor (707)

Christian Fuchs, Sascha Wolf

Firefly-Algorithm

Algorithm 1: The Firefly Algorithm

Figure: Firefly-Algorithm

- Goal: Minimize damage by assigning firefighters to high-risk areas
- Interest in estimated reward: $\hat{k_{i,t}} = k_{it}$, if i is covered
- Otherwise: $\hat{k_{i,t}} = \frac{1}{t-1} * K_{i,t-1}$ and K = cumulative reward
- Distribution of firefighters by maximizing the sum of the reward of each zone

Firefly-Algorithm

Figure: red: high-risk area; green: save area

- **Performance measurement:** Number of red zones to which firefighters are sent to
- Compare which version performs better

- Spark allows us to simulate specific wildfire in fixed Area
- We can change and create new data
- We're able to take the simulated data and analyze them in weka
- Through the analyzed data we get the Possibility to calculate risks through flame height and arrival time
- this data we compare to our machine learning Alg

- Collect more data with simulation to train Machine-Learning Algorithm
- Implement a third Machine-Learning Algorithm and compare to the other two
- Final: Compare performance of the Firefly-Algorithm based on presented formula
